Name: Ashley Zapata Minero

TAC 303 - Full Stack Web Final Project Summary

1. **Explain the topic and purpose of your site.**

   My topic is a language learning hub centered website. The purpose of this website was to provide Japanese language learners with the tools to have a self study management system, where they can get motivation through quotes. They can create their own tasks associated with learning Japanese. As well as creating their own blogs, and giving them inspiration for topics to use. A cool part I thought would be interesting was adding a topic I learned in school which I thought would be very helpful for learning language which is Natural Language Processing particularly POS (part of speech) tagging that would make it easier for language learners to break down the language.

2. **Provide instructions on how your site works (admin credentials, password-protected pages, etc.).**

   I implemented the login and registration system, so anyone can create a password and login. However if you do want to use an existing account I created one where I was testing the functionalities the credentials are as follows:

   - Username: Princess
   - Password: Princhan1

3. **Explain the source of your data.**

   The source of my data varied, since it is a language learning hub. I let users create their own dynamic data and preserve it through the database. However, I did use some data from a third party api called kotowaza which has quotes, and I got them randomly. I also for my sentence recommendation systems I used a dataset of my own hard coded sentences which it randomized between using Javascript. I also used some of my own personal data from Japanese blogs that I did to populate the dataframe. Only like two to populate it and be able to display it in the account I was testing on.

4. **Attach Database Diagram (screenshot or PDF file).**

5. **Describe features you implemented.**

    a. [3rd party Kotowaza API] - I used this 3rd party API, in order to use the functions they have through their API, such as randomly regenerating a quote from their system, and requesting it so it could be displayed in my quote section.

    b. [React-timer-hook] - I used this React client side library in order to create my pomodoro system. I used the features it has such as pause, start, or also the time stamp system they had. I think using it helped facilitate making the timer.

    c. Authentication - implemented Registration and Logging users coming from the database. By also attaching all their tasks connected to the user, and also all blogs were connected to the user. The tasks themselves knew which user had them so for pomodoro i didn't include the user cause it's connected and can be derived from connecting views(small tables to view the entire information via left join).

    d. Event driven DOM manipulation - I used in my task system allowed users to delete the object via (x) button. I also allowed the user to add/create a new task they had generated (+). I also allowed the user to edit/update the

already existing task via (edit) button, and I also read the information to the user by displaying the tasks there for the user. I used all these buttons from google font icons.

e. Form creation - created many forms, one of them was for the Task Manager. Another form was for creating the blogs and another was for the pomodoro timer. Also for the Registration and Login they were forms as well.
f. React Router Library - I used this library to facilitate going through pages, since React is a single page application, using the router helped me show only the components I wanted in each respective route.
g. Many to many relationships - implemented many to many relationships with the Task Manager and the pomodoro such that a user can choose which task they want to work on and the timer gets updated to the time they had set in the Task Manager.

6. Describe CSS frameworks or templates used. Provide links to original files.

    a. Most of my code was created by me, such as the design. But I did use Bootstraps form design and implemented their classes because I liked the ui and how easy it was to implement.
